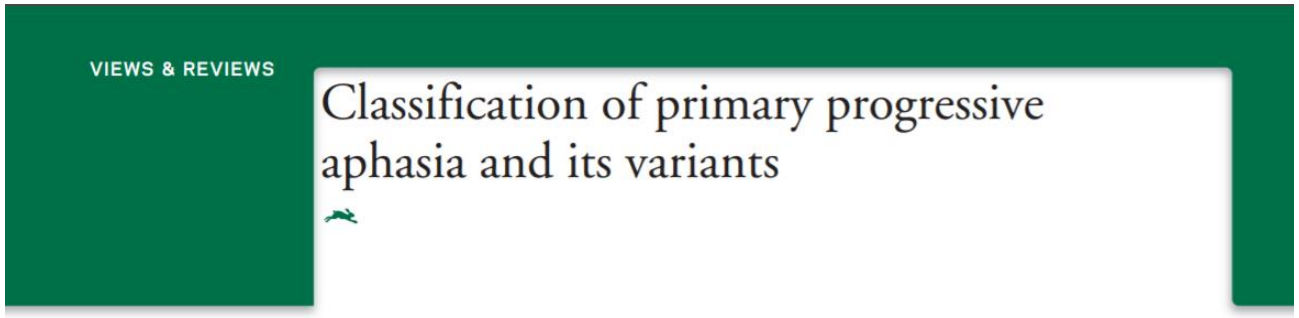
PRIMARY PROGRESSIVE APHASIAs



Heterogeneous clinical phenotypes are associated with the PPA (nf-PPA, sem-PPA, lv-PPA) , and recent review studies refer to Alzheimer disease (AD), corticobasal syndrome (CBS) and progressive supranuclear palsy (PSP)

The topography of FDG PET brain hypometabolism represents the major signature of the clinical PPA phenotype

PARKINSONIAN SYNDROMES

The Parkinsonian Disorders (APD) frequently overlap in clinical presentations, making the differential diagnosis challenging, particularly in the early stages

Low dopamine transporter uptake at SPECT is present in all the parkinsonian syndromes making its role in the differential diagnosis of APD not possible

The dysfunctional brain patterns revealed by FDG PET represent biomarkers of local synaptic dysfunction associated with disease-specific alterations characterizing APD conditions

THE CLINICO-METABOLIC CORRELATES OF LANGUAGE IMPAIRMENT IN CBS and PSP

70 patients fulfilling current criteria for probable CBS (n=33) or PSP (n=37)

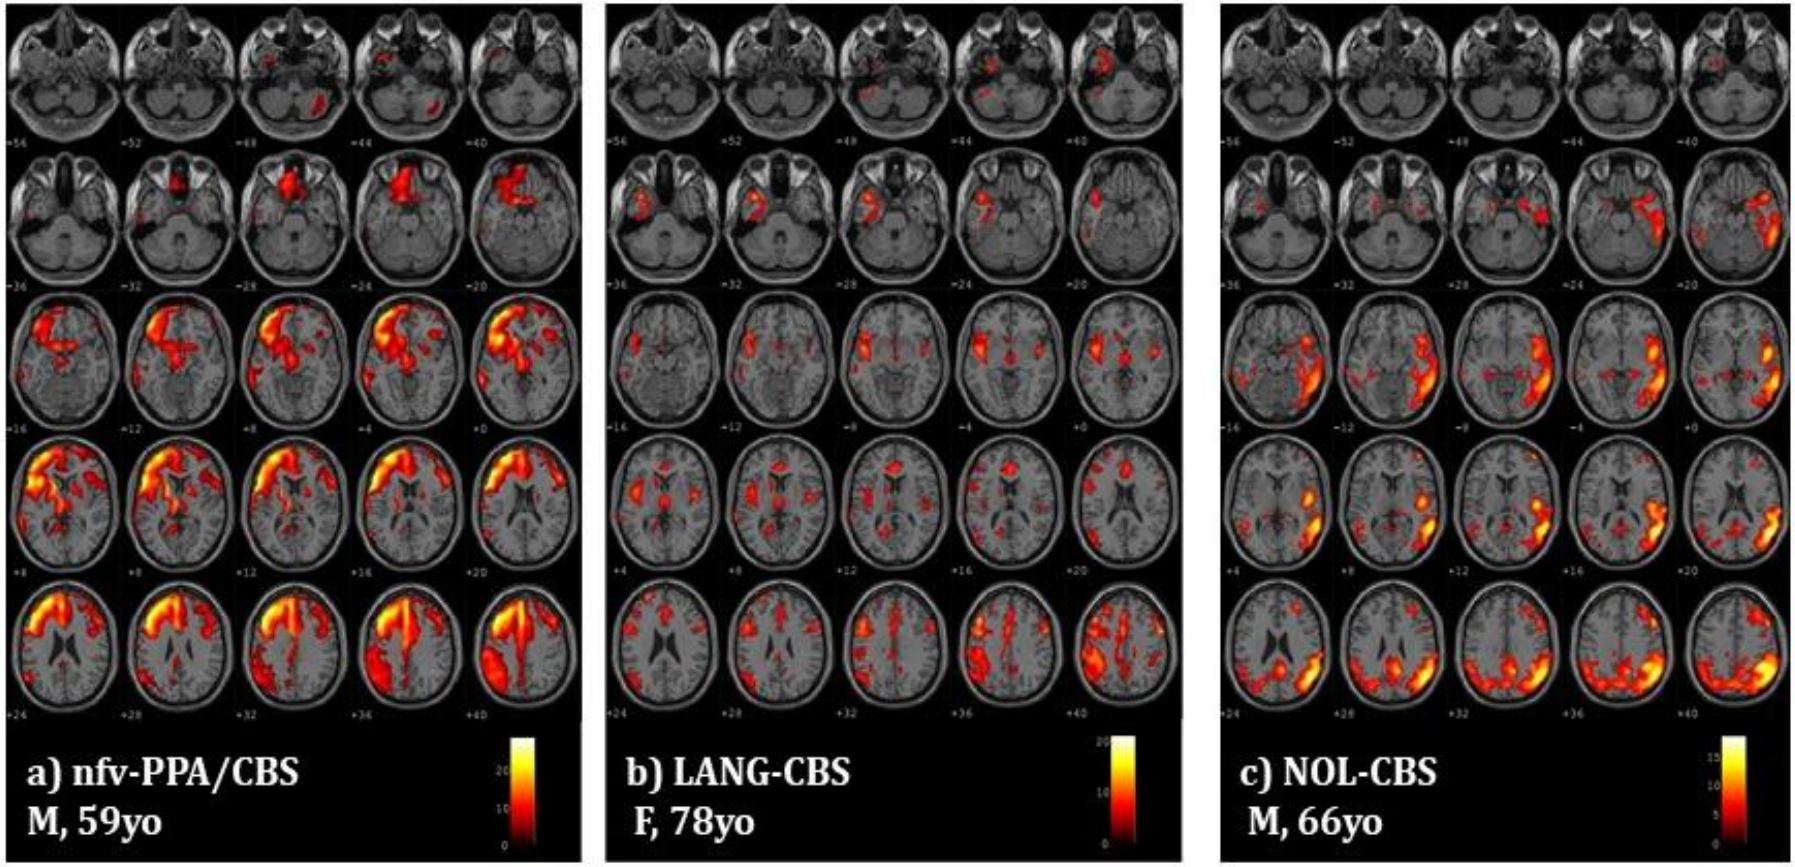
All subjects underwent clinical-neuropsychological and FDG-PET assessments at the time of diagnosis.

The whole patient's cohort was grouped into three subgroups according to the language characteristics:

- **nfv-PPA** *(anomia, agrammatism, impaired comprehension of single words or complex sentences)*
- **subtle language impairments** *not fulfilling nfvPPA criteria*
- **no language deficits**

Dodich et al. NI Clin 2019

SPM maps of significant FDG-PET hypometabolism at the single-subject level in CBS subjects with different language profiles



Dodich et al. NI Clin 2019

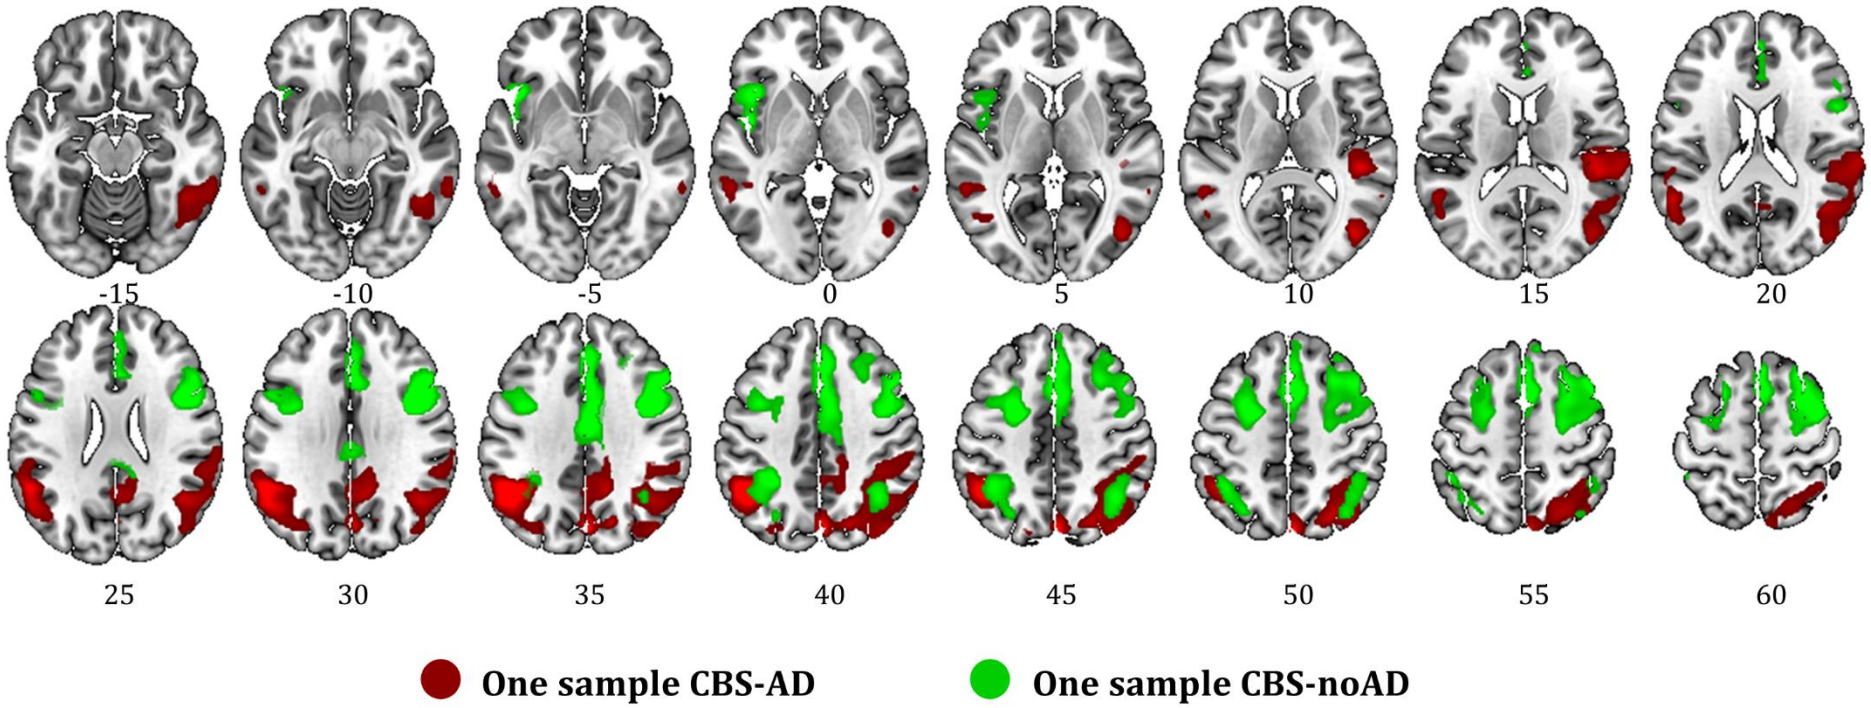
BRAIN METABOLIC SIGNATURES OF CBS DUE TO AD OR NON-AD PATHOLOGY

CBS is the common clinical presentation of patients with CBD pathology

Nevertheless, there are individuals with post-mortem neuropathological changes typical of AD that may show an undistinguished CBS clinical phenotype

Cerami et al. submitted

FDG PET hypometabolism maps



These results suggest the inclusion of FDG-PET imaging in the diagnostic algorithm of individuals with CBS clinical phenotype in order to early identify functional metabolic signatures due to different neuropathological substrates, thus improving the diagnostic accuracy

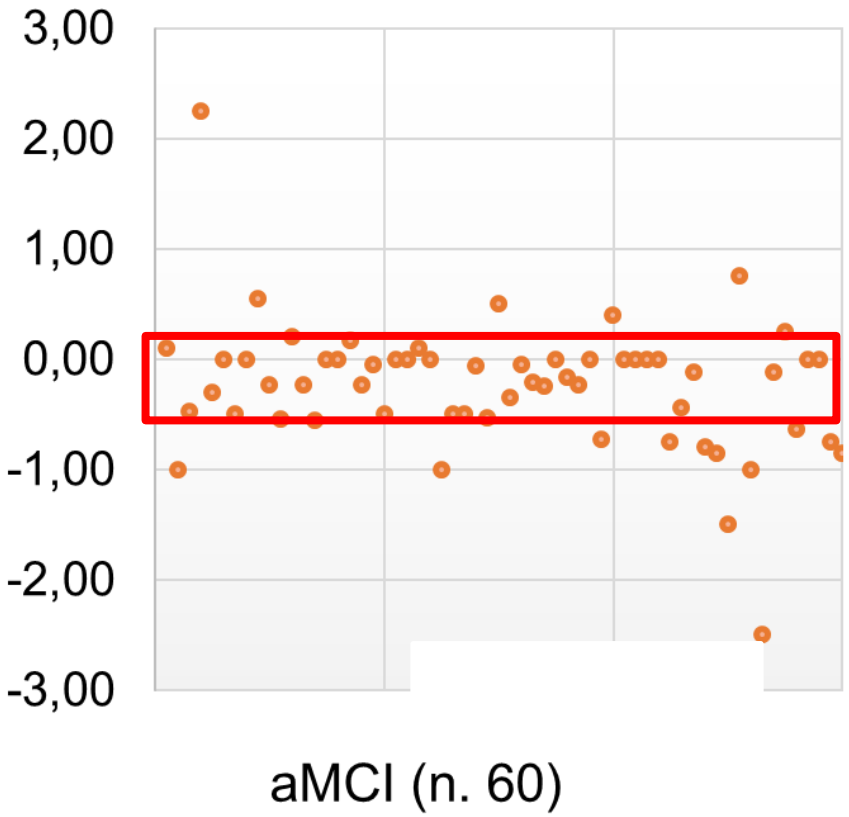
Nessun aMCI progredisce a demenza

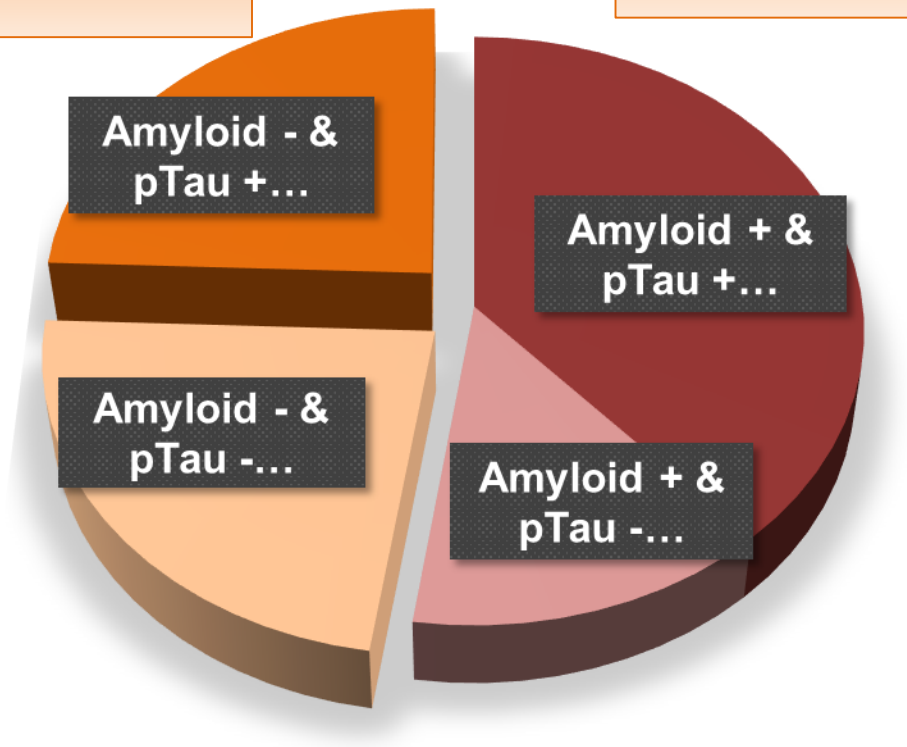
INDICE DI PROGRESSIONE
(MMSE follow-up – MMSE baseline)
anni di follow-up



According to FDG PET and CSF values

N+ and Non AD pathological changes 48%

N+ and AD pathological changes 52%



FDG-PET Sensitivity for Clinical Stability

$$\text{Sensitivity} = \frac{\text{Number of true positive}}{\text{Total number of patients}}$$

$$\text{Sensitivity} = \frac{80}{86} = 93.02\%$$

Only 6 out of 86 aMCI subjects presented abnormal MMSE score at last follow-up

CONCLUSIONI

Soggetti con aMCI e pattern FDG-PET temporo-mesiale e limbico mostrano un'evoluzione clinica benigna, caratterizzata da non progressione a demenza

I biomarcatori liquorali non contribuiscono alla diagnosi e sono ininfluenti nel caratterizzare la stabilità clinica

L'unico biomarcatore con valore diagnostico e prognostico predittivo di stabilità è il metabolismo cerebrale valutato con FDG-PET

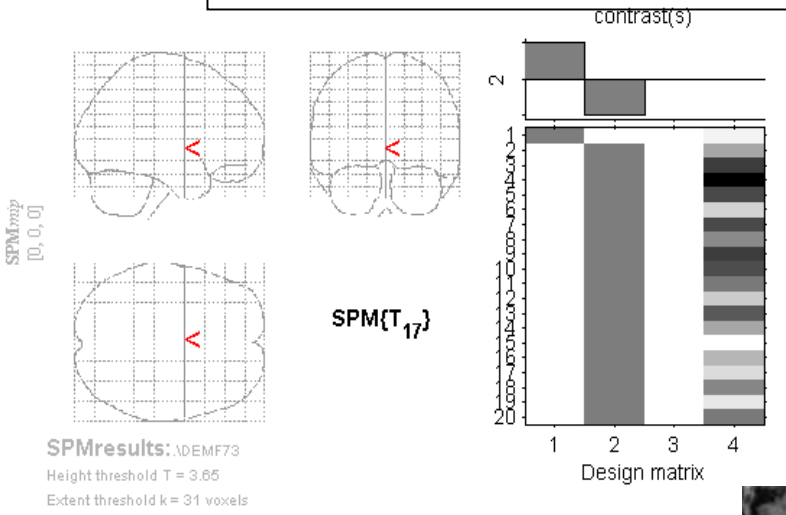
Eziologie possibili: limbic predominant age related TDP-43 encephalopathy, argyrophilic grain disease, primary age related tauopathy

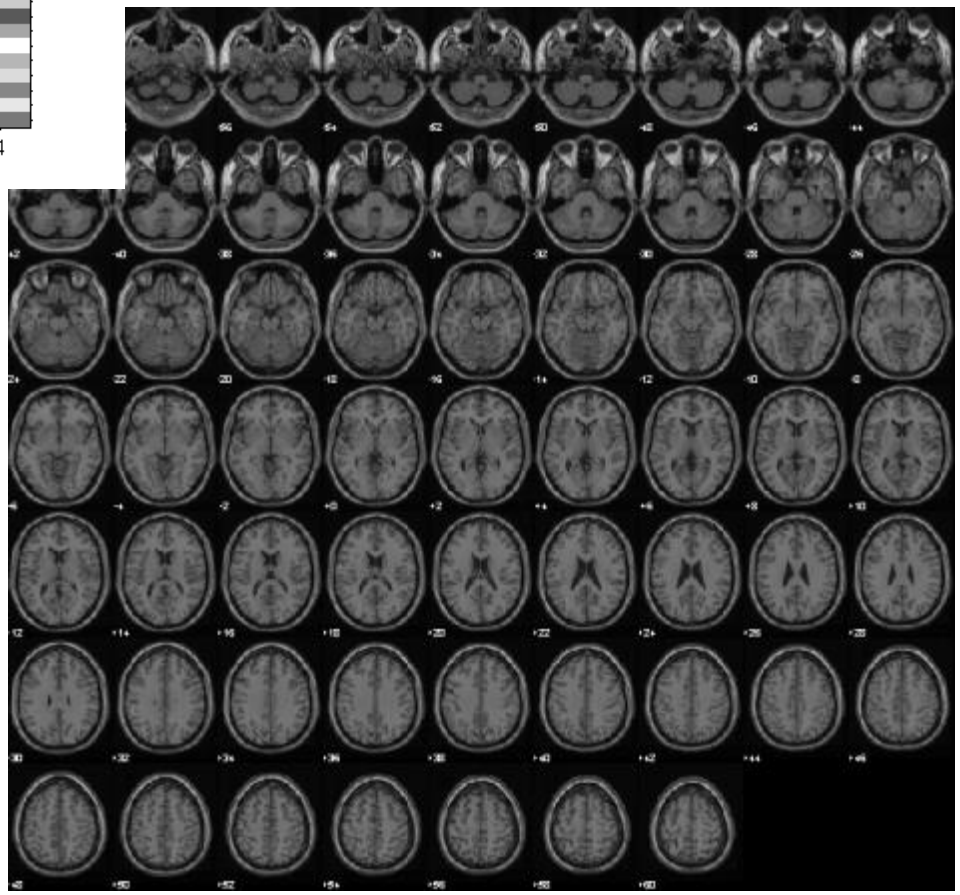
Crary et al., Acta Neurop 2014; Ferrer et al., Brain 2008; Cerami et al. 2018, Nelson et al., Brain 2019

Diagnostic challenge

Exclusionary role

aMCI ♀ 62 years old





NO Neurodegenerative disease exclusionary role!

FDG PET EXCLUSIONARY ROLE

A crucial aspect that posits FDG PET measures as the most supportive finding of neural dysfunction and neurodegeneration is that **clinical symptoms never occur without brain metabolic decreases**, the extent of which is related to the severity of cognitive impairment

All the above and the high specificity of FDG PET in AD, FTLD and DLB implies that **a negative, or normal scan in the presence of the suspicion of dementia makes a diagnosis of a neurodegenerative disease very unlikely**

The accuracy measures available with FDG PET near the time of initial diagnosis of dementia is similar to longitudinal clinical diagnosis over 3–4 years, thus **in the context of initial diagnosis, the exclusionary role of FDG PET is especially important** in younger subjects with a suspicion of neurodegenerative disease.

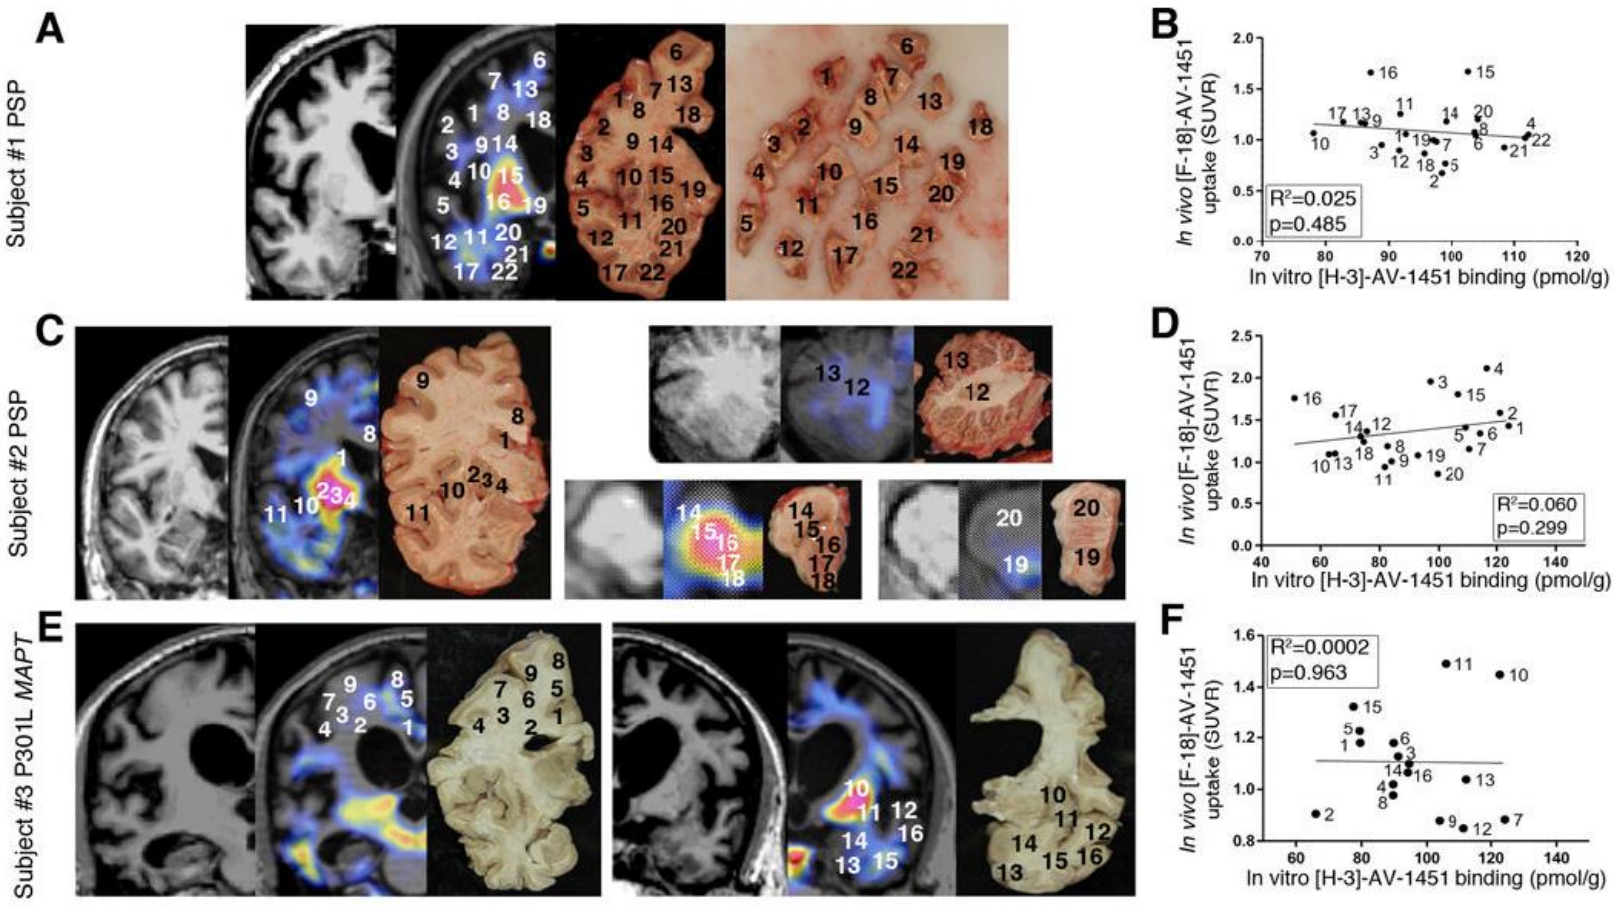
Johnson, MD[2], and Teresa Gómez-Isla, MD, PhD[1,2]

Interpretation AV-1451 may have **limited utility** for in vivo selective and reliable detection of tau aggregates in these non-Alzheimer tauopathies

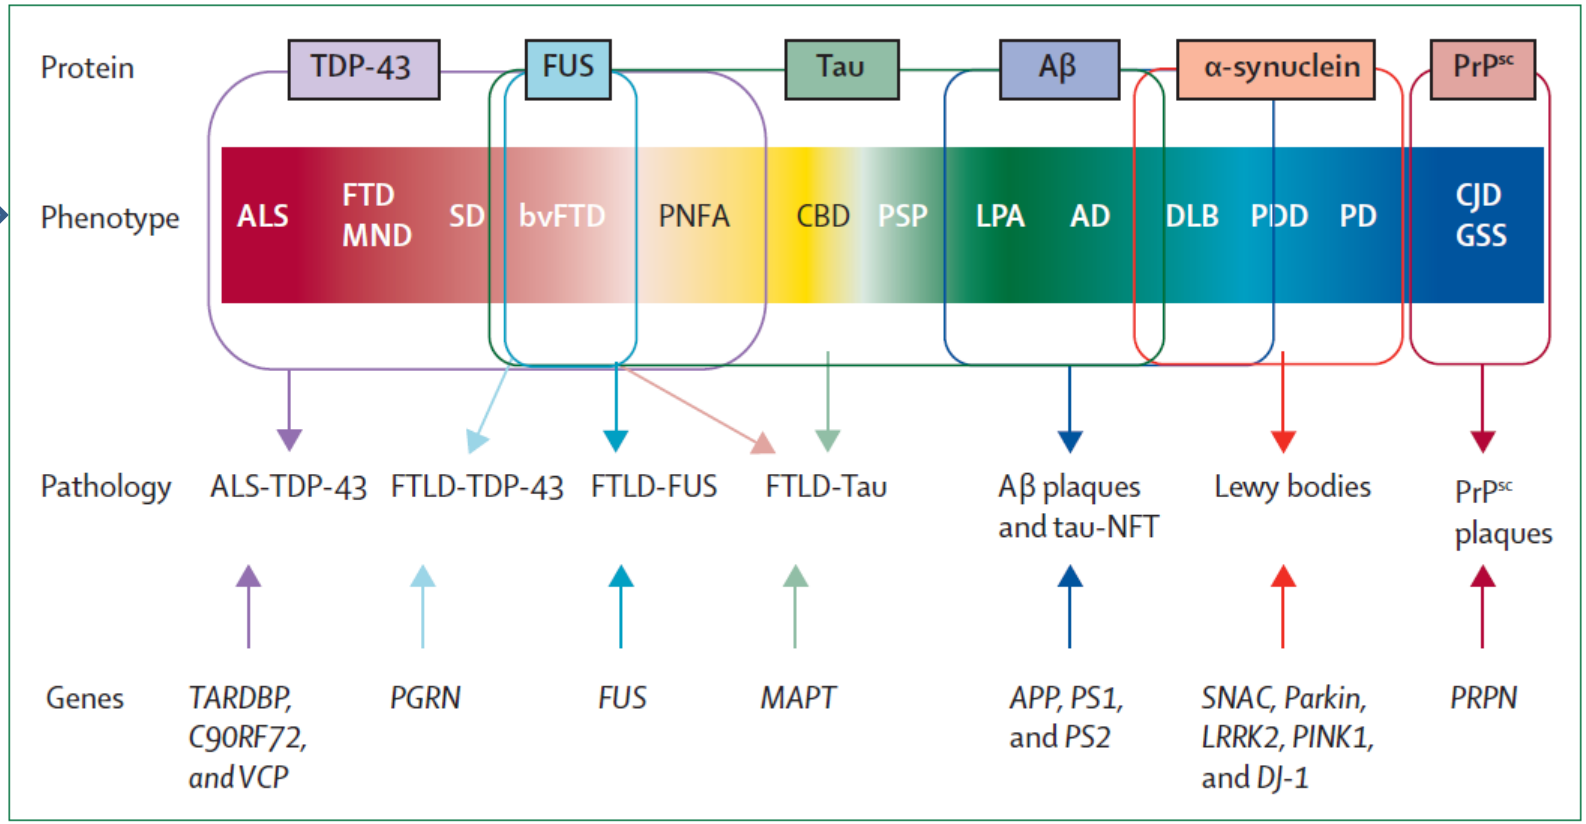


Images from coronal brain sections of MRI (left) and their corresponding [F-18]-AV-1451 PET scans (middle) and autopsy tissue blocks (right)

Pros and Cons

Tau aggregates	Tracers	Strengths	Weaknesses	Technical caveats
• AD dementia • MCI • DLB • CBD • PSP • CTE • DS • Genetic FTD • Healthy aging	• [11C]PBB3 • **[18F]Flortaucipir** • [18F]THK family	• *in vivo* detection of brain deposition of neurofibrillary tangles in AD, consistent with *post-mortem* autopsy findings • Tight relationships with ND and cognitive impairment in AD • track AD disease progression • evaluate tau therapies in clinical trials	• Presents non-specific binding in choroid plexus and neuromelanin-containing tissue • Pathologies characterized by predominant 4R tau and TDP-43 present weaker binding increases when compared to AD tauopathy • Medial temporal lobe tau accumulation is present in healthy aging • [18F]THK5351,non-specific binding to MAO-B	• Seems not to reach steady state in 100 minutes • Semi-quantified measurements are needed • Neuropathology studies are needed

PHENOTYPES, GENETICS, PROTEINOPATHIES IN NEURODEGENERATIVE DEMENTIA



Seelaar et al., J Neurol Neurosurg Psychiatry, 2011

A NEW PERSPECTIVE

Last years are witnessing a rapid transition from a **clinical-based** to a **pathology-based classification** of neurodegenerative conditions, largely promoted by the **increasing availability of molecular neuroimaging biomarkers**

This implementation promotes a **spectrum-approach to neurodegenerative conditions**, based on **pathology subtypes** and **clinical endophenotype heterogeneity**

Descriptive meta-analysis from the relate literature
Color gradients index magnitude of alteration

A NEW PERSPECTIVE

This approach will enhance efforts to understand both the biology of Alzheimer's Disease as well as the multifactorial etiology of other dementias, which has been obscured to some extent in the past by equating the PET protein molecular biomarker role to an effective diagnostic tool

Together with methodological challenges in the production of these tracers, their optimal quantification and standardization procedures, and their evidence-based clinical utility
